INTRODUCTION

The phenomenon of aging in nowadays society has acquired the status of a social problem, with growing attention and concern, leading to an increase number of studies dedicated to the elderly. [1-3] The lack of domestic, familiar or social support often lead elderly to nursing homes. Institutionalisation is in many cases the only opportunity to have access to health care and life quality. [1,2]

Aging is also associated with a higher prevalence of chronic diseases that require long term medication sometimes for life. Frequently the onset of multiple pathologies at the same time require different therapies and the phenomena of polypharmacy (five or more drugs daily) can occur. Even more, the slow down of physiological and cognitive mechanisms associated with these chronic diseases can interphere, in one hand, with the pharmacokinetics of many medications and, on the other hand, with the facility to accomplish the therapeutic regimen. All of this realities contribute to an increase of pharmacotherapeutical complexity, decreasing the adherence and effectiveness of treatment. [1,2,3,4]

The pharmacotherapeutical complexity of an individual is characterized by the conglutinating element of different characteristics of their drug therapy, such as: the number of medications used; dosage forms; dosing frequency and additional indications. It can be measured by the Medication Regimen Complexity Index (MRCI), originally validated in English by Johnson et al. [4]

METHODOLOGY

OBJECTIVE

Determine the pharmacotherapeutical complexity index in institutionalized elderly in the interior and littoral regions of Portugal, between February and September 2009 by the MRCI.

STUDY DESIGN

Cross-sectional study.

LOCAL OF DATA COLLECTION

Five nursing homes divided by Évora and Lisbon-districts.

DATA COLLECTION INSTRUMENT

Form based in MRCI.

DATA PROCESSING & STATISTICAL ANALYSIS

SPSS, Version 16.0 using Pearson correlation and T student test.

RESULTS

The results refer to five nursing homes, two located in the interior and three located in the littoral, contributing to a sample with 220 and 205 elderly, respectively.

The sample submitted is mainly female, 60.24%, but as age progresses, the difference between the genders decreases.

Top five drugs most consumed

The results for the daily consumption of each drug revealed that elderly took an average of 8.22 +/- 3.56 drugs per day, a range that varies between a minimum of 1 and a maximum of 20 drugs.

The average daily consumption of drugs was higher among women, 8.9 +/- 3.29 drugs than in men, 7.2 +/- 3.57 drugs, both in the interior, 8.37 +/- 3.36 drugs and littoral, 8.06 +/- 3.75 drugs.

The polypharmacy was found in 85.5% of the sample.

The more common dosage form in the pharmacotherapy were tablets and capsules, 94.5% of the total.

Of all the drugs consumed, the most prevalent were for the cardiovascular system (39.8%), nervous system (27.7%) and gastrointestinal system (19.9%).

The drug most commonly used, was Acetylsalicylic acid 100mg and 150mg, as an antplatelet aggregation agent, with 31.8%.

The Acetylsalicylic acid integrates the WHO guidelines for cardiovascular disease, in patients with cardiovascular risk, with an initial dose of 75mg per day. [5-10]

Benzodiazepines as a therapeutic class were present in the pharmacotherapy of 40% of the sample, mainly due to the syndromes of anxiety and sleep disturbances observed in the elderly. [1,2,3,4]

The MRCI average was 18.24 +/- 9.66, between a minimum of 2 and a maximum of 53.5. The MRCI was higher in the interior, 18.94 +/- 9.86 compared to the littoral, 17.52 +/- 9.86 and much higher in women, 19.63 +/- 9.22 compared to men, 16.14 +/- 9.98.

According to the Pearson Correlation, the MRCI grew as the number of medications consumed increased. The greater the age, the lower the MRCI and the number of medications consumed, contrary to what is normally reviewed in the literature. [11,12]

The correlation observed between the MRCI and its three sections (A, B and C) shows the direct contribution of each to the growth of total MRCI. The section B, dosing frequency, was the largest contributor to the increase in the MRCI.

Statistical tests showed no significant differences in the MRCI and the number of medications consumed between genders, regions and presence or absence of a health professionals in the pharmacy of the nursing home.

CONCLUSIONS

The MRCI showed to be an important tool in monitoring pharmacotherapeutical complexity in nursing homes of Portugal. This type of follow up, can contribute to the reduction of problems associated with drugs in this group of people and increase adherence to therapy in the institutionalised elderly. The pharmacotherapeutical complexity were mainly higher, predicting the need for further intervention in the pharmacotherapy of institutionalized elderly.

The prospect for studies in this area is vast as the problems of elderly and their pharmacotherapy urges for future research.
